

When should you work with branches?

When we are collaborating with other people. When working alone, branches can add unnecessary complexity. But when it comes to collaboration, branching offers a safe way that we can divide tasks and define isolated development paths where everyone can work on a part of the project with minimal conflicts.

What is the difference between a git clone and a git fork?

Cloning a repository means copying it from a remote repository to a local directory, allowing us to work on it or use it on a device. In contrast, forking a repository involves creating a new remote repository based on an existing one. The key difference is the destination: cloning is from remote to local, while forking is from remote to remote.

What is the difference between a fork and a branch?

The main difference lies in how a repository is managed. When using branches within a repository, every commit needs to be done or approved by the maintainer. In contrast, forking a repository allows for more localized management, enabling contributors to work with greater freedom. This approach allows maintainers to be less involved in the intermediate steps taken to achieve a goal. They only look at the final changes when the forked repository requests a pull.

What advantages and disadvantages to code review can you imagine/list?

Code review is an essential step, especially for complicated tasks that require critical changes in the program. While solving an issue, we may create more issues in other parts or inconsistencies throughout the project. Code review also creates an opportunity to use the ideas from other collaborators. I see basically no disadvantage, other than a little slowing down of the process in case of some minor changes. Overall, the advantages are more obvious.
